BENEFITS OF STAINLESS STEELS FOR UTENSILS

Dr. Arijit Saha Podder
History

**Harry Brearley** is usually credited with the invention of stainless steel. However, it wasn’t until 1911 that the importance of a minimum chromium content was discovered by Germans P. Monnartz and W. Borchers.

In metallurgy stainless steel, also known as inox steel or inox, is defined as a steel alloy with a minimum of 10.5% chromium content by mass.

Stainless characteristic of these steels are achieved through formation of an adherent, a very thin layer of about 130 Å chromium-rich oxide film on the surface due to higher affinity of chromium for oxygen. This layer is passive, tenacious and self healing.
Genesis of 200 Series

- Chrome-manganese grades were first developed in the early 1930s.
- 15Cr-12Mn-1.5Ni Stainless steels were in use in Germany in 1940’s. Major applications were in dairy industry, beer industry and household appliances.
In early 50’s during Korean War US Govt. put restriction of 1% Ni max for stainless steel in certain applications

Following grade developed by Allegheny, for the manufacture of railcars, termed as IA 201

**Post Korean War Scenario**

- Softer alloys preferred
- Half of Nickel only replaced by Mn and N
- AISI Designation in 1955 to 201 and 202
History of 200 series in India

- Started in early 1990’s
- Various steels with different Ni content from 6% to 0.2%.
- The development was initiated to cater the domestic market of utensils, with low cost stainless steel.
- The technical theme behind development of these grades was mainly to substitute the costly nickel with manganese and nitrogen to achieve the austenitic structure.
- With the growing popularity and increased knowledge on the in-service properties of such steel across India, this steel could also find high-end applications in the field of consumer durables, catering and food processing industry, architecture, transport, building and construction.
Role of alloying elements

Manganese
Manganese is added to steel to improve hot working properties and increase strength, toughness and hardenability. Manganese has THREE main effects to aid the stability of stainless steel:
• promotes the formation of austenite
• combines with the sulfur to form manganese sulfides
• increases the solubility of nitrogen

Nickel
The reason for Nickel addition is to promote an austenitic structure. Nickel generally increases ductility and toughness. It also reduces the corrosion rate and is thus advantageous in acid environments.
**Chromium**
Most important alloying element in stainless steels, it provides stainless steels basic corrosion resistance. It also increases the resistance to oxidation at high temperatures.

**Nitrogen**
Nitrogen is a very strong austenite former. It also substantially increases the mechanical strength. Moreover, Nitrogen improves the resistance to pitting.

**Copper**
Copper enhances the corrosion resistance and stress corrosion cracking resistance in certain acids and promotes an austenitic structure. Presence of copper also increases ductility.
Improvement in drawability of AISI 201 by alloying with Cu

By addition of 1.5-2% Cu to AISI 201, a stainless steel with superior drawability was evolved.

Effect of Cu on strain hardening exponent of stable austenitic stainless steel at several Ni levels.
With the development of
- Argon Oxygen Decarburisation
- Ladle Refining
- Continuous Casting
- Rolling Temperature Control

Leaner alloys produced successfully with controlled N, P and S.

These alloys are endowed with high strength, good drawability, weldability and corrosion resistance.

- 8Mn2Ni
- 7Mn4Ni
- 304

Drawing Height (h/l) vs. $r_c/l$
Suitability for Food Equipment/Contact Material

- 8Mn2Ni with 16%+ Cr fully conforms to American National/International Standard ‘NSF ANSI 51’ for food equipments/contact material.

- It is suitable for this purpose as per policy statements of ‘Council of Europe’ and ‘Ministere de L’Economie des Finances et de L’Industrie’ of French Republic.

- It meets stipulation of Minister’s Decree 21.3.73 and successive updates of 26.4.93 and 28.10.94 in Italy for suitability as material for utensils in contact with food substances.
The X-factors

- Good ductility along with high strength
- Scratch Resistance
- Better Polishability
Application of 9Mn1Ni

- Shallow/medium drawn utensils
- Cutlery
- In-house Water tanks
Applications of 8Mn2Ni

- Deep drawn utensils
- Ice & Water Dispensers
- Milk cans
- Industrial kitchen equipments
- Cookware
- Water Filters
Applications of 7Mn4Ni

- Extra Deep drawn utensils
- Pressure Cookers
- Hot Food Wells
- Cook line
- Beverage Dispensers
Like 304, 8Mn2Ni is fully austenitic in annealed condition.

Martensite formation in 8Mn2Ni on cold working is much less compared to 304.

Work hardening rate of 8Mn2Ni is lower as compared to AISI 201.

Corrosion tests have been conducted in NaCl solution and organic food media.

Sodium chloride solution was selected as one of the media as chloride ion is notorious for its ability to penetrate passive films and cause pitting. Sodium chloride is also a common ingredient in food preparations. Brackish water which carries 3% NaCl, which is selected for immersion tests.

Acetic acid is present in vinegar and it is common to use vinegar in kitchen. When milk deteriorates, lactic acid is produced. Hence a mixture of lactic acid and acetic acid was chosen as second medium.

Citric acid is commonly present in fruit juices and tartaric acid is an ingredient in tamarind extracts. Hence, the concentration of 10000 ppm (1%) of a mixture of two acids was chosen to get accelerated results.
